A Priority-Based To-Do and Routine Planner

Student Names: [Names]
Roll Numbers: [Roll Numbers]
Guide Name: [Guide Name]

Department: [Department]
College Name: [College Name]

Introduction

01 Daily planning includes both one-time tasks and repeating habits.

02 Fais gives each user a private place to organize their day.

03 A playful routine board and calendar make progress visible.

Problem Statement

01 Scattered notes make it easy to lose track of small commitments.

02 Unclear priorities make the next task difficult to choose.

03 Repeated routines need date-specific tracking and a useful history.

04 A task list alone offers limited visibility into daily consistency.

Objectives of the Project

01 Organize tasks with clear priorities, deadlines, and status.

02 Track repeating routines without losing earlier completion records.

03 Restore saved data across refreshes and authenticated sessions.

04 Support desktop and mobile access with visible progress.

Scope of the Project

01 Implemented: personal accounts, task CRUD, priorities, and search.

02 Implemented: routines, calendars, statistics, activity, and settings.

03 Implemented: autosave, retries, and responsive web navigation.

04 Excluded: Android app, notifications, offline sync, teams, and mood journal.

Existing System

01 Paper lists provide a simple record, but updates and summaries are manual.

02 Basic digital lists organize items but vary in recurring-task support.

03 Modern planners already offer many advanced planning features.

04 Fais focuses on a coherent personal workflow and explainable MERN design.

Proposed System

01 A user signs in to a MongoDB-backed session.

02 Tasks use High, Medium, and Low priority with deadline ordering.

03 Routine check-ins belong to one routine and one local calendar date.

04 Calendar, statistics, and activity read persisted records.

Hardware and Software Requirements

01 Verified environment: Apple Silicon Mac, macOS 26.6.2, Node 24.14.0, npm 11.9.0.

02 Required software: MongoDB 8.0, Git, a modern browser, and project dependencies.

03 Practical recommendation: 8 GB RAM and several GB of free disk space.

04 Network: package installation and optional fonts or Atlas. Compass is optional.

Technology Used

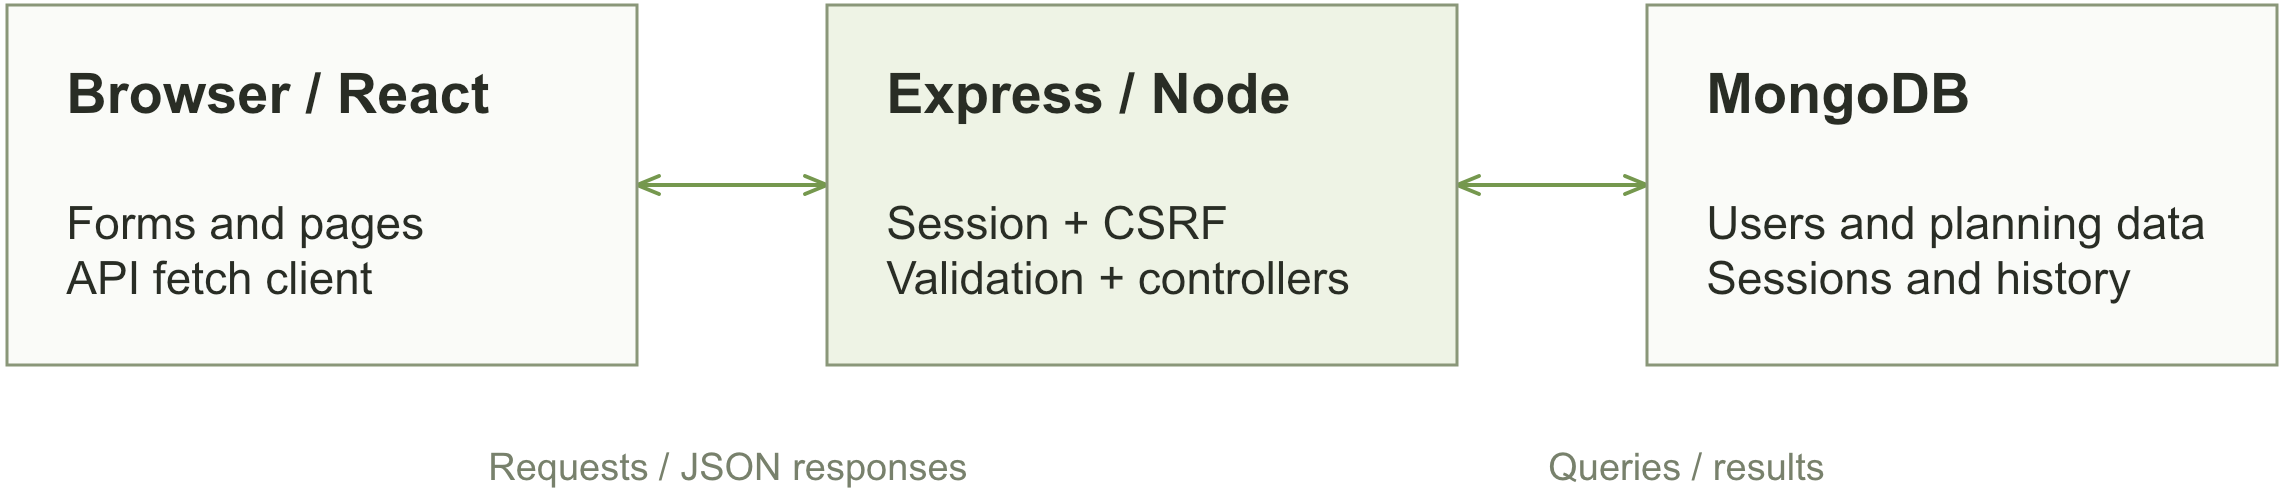

01 React + Vite: pages, reusable components, routing, and production builds.

02 Node.js + Express: REST endpoints, validation, and ownership checks.

03 MongoDB + Mongoose: records, indexes, persistence, and version checks.

04 bcrypt, sessions, and Luxon: password hashing, authentication, and local dates.

Block Diagram

Ownership and business rules stay on the server.

Modules of the Project

Authentication

Registration, login, session restoration

Routines

Schedules, ordering, archive, and daily check-ins

Autosave / Activity

Serialized saves, retries, and action history

Tasks / Priority

CRUD, filtering, status, and racing progress

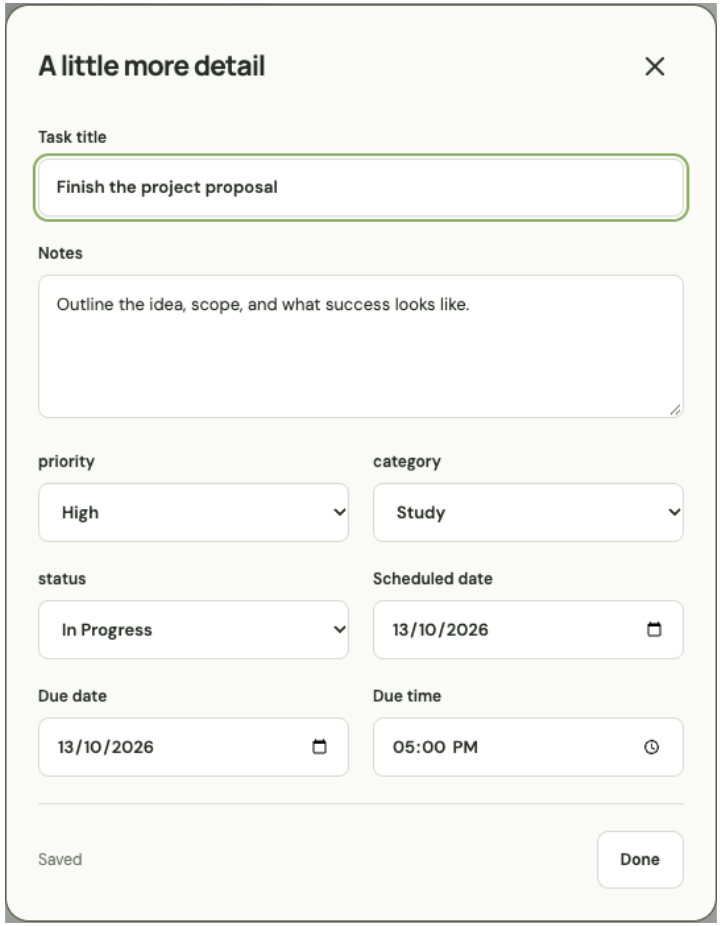

Calendar / Statistics

Occurrence rates, daily counts, and streaks

Settings

Name and IANA timezone

Screenshots / Output

Task details with confirmed autosave

Routine board with independent daily check-ins

Future Scope

01 A native Android client that reuses the Express API.

02 Reminders and notifications with user-controlled scheduling.

03 Offline synchronization with explicit conflict handling.

04 Shared planning, an optional mood journal, and native widgets.

Conclusion

01 Fais combines one-time tasks and repeating routines in a working MERN app.

02 Confirmed MongoDB data survives refreshes and session restoration.

03 Focused tests check isolation, date rules, ordering, and save reliability.

04 The project provides a foundation for further native and offline features.
